Unlocking the Power of Algebra: Practical Word Problem Examples with Solutions

Algebra can sometimes feel like a mysterious language, filled with x's and y's that seem detached from the real world. But the truth is, algebra is a powerful tool for problem-solving, and word problems are its most direct application. These are the puzzles that bridge the gap between abstract equations and tangible scenarios, helping us make sense of everyday situations, from calculating distances to managing finances. In this comprehensive guide, we'll dive deep into the world of algebra word problems, exploring various types with clear, step-by-step solutions. Whether you're a student grappling with homework, a parent helping with math, or just curious about how algebra works in practice, you'll find valuable examples and insights here. We'll focus on

making these problems accessible and demonstrating how to approach them with confidence.

Why Are Algebra Word Problems So Important?

Before we jump into specific examples, let's touch upon why mastering word problems is so crucial.

1. **Real-World Relevance:** Word problems are designed to mimic real-life situations. Solving them helps you see how mathematical concepts are applied outside the classroom.
2. **Critical Thinking Skills:** They demand you to analyze information, identify the unknown, and strategize the best way to find a solution. This hones your analytical and logical reasoning.
3. **Building Confidence:** Successfully tackling a challenging word problem can significantly boost your confidence in your mathematical abilities.
4. **Foundation for Advanced Math:** A strong understanding of word problems is essential for more complex topics in mathematics, science, and engineering.

Let's get started with some common types of algebra word problems and how to solve them.

1. Age Problems: Figuring Out the Years

Age problems are a classic in algebra. They involve relationships between the ages of people at different points in time. The key is to set up equations that represent these relationships. **Example 1:** Sarah is currently twice as old as her brother Tom. In five years, Sarah will be 10 years older than Tom. How old are Sarah and Tom now? **Keywords:** age, older, younger, in five years, currently **LSI Keywords:** age difference, future age, present age, relative age **Solution:** Let S represent Sarah's current age. Let T represent Tom's current age. From the first statement: "Sarah is currently twice as old as her brother Tom." This translates to the equation: $S = 2T$ (Equation 1) From the second statement: "In five years, Sarah will be 10 years older than Tom." In five years, Sarah's age will be $S + 5$. In five years, Tom's age will be $T + 5$. The relationship becomes: $S + 5 = (T + 5) + 10$ (Equation 2) Now we have a system of two linear equations: 1. $S = 2T$ 2. $S + 5 = T + 15$ We can use substitution to solve this. Substitute the value of S from Equation 1 into Equation 2: $(2T) + 5 = T + 15$ Now, solve for T : $2T - T = 15 - 5$ $T = 10$ So, Tom's current age is 10 years old. Now substitute $T = 10$ back into Equation 1 to find Sarah's age: $S = 2 * 10$ $S = 20$ Therefore, Sarah's current age is 20 years old. **Check:** Currently, Sarah (20) is twice as old as Tom (10). This is correct. In five years,

Sarah will be 25 and Tom will be 15. Sarah (25) will be 10 years older than Tom (15). This is also correct.

2. Distance, Rate, and Time Problems: The Journey of Numbers

These problems are fundamental for understanding motion. The core formula is ****Distance = Rate $\times$ Time (D = RT)****. The trick is to correctly identify what information is given for each object or scenario. **Example 2:** A train leaves a station traveling at 60 miles per hour. Two hours later, a second train leaves the same station on a parallel track, traveling at 80 miles per hour. How long will it take the second train to catch up to the first train? **Keywords:** distance, rate, time, miles per hour, train, catch up, parallel track **LSI Keywords:** speed, travel time, relative speed, overtaking **Solution:** Let t be the time (in hours) the second train travels until it catches up to the first train. The first train travels for 2 hours longer than the second train. So, the time the first train travels is $t + 2$ hours. The speed of the first train (R_1) = 60 mph. The speed of the second train (R_2) = 80 mph. When the second train catches up to the first train, they will have traveled the same distance. Distance traveled by the first train (D_1) = $R_1 \times (t + 2) = 60(t + 2)$ Distance traveled by the second train (D_2) = $R_2 \times t = 80t$ Since $D_1 = D_2$: $60(t + 2) = 80t$ Now, solve for t : $60t + 120 = 80t$ $120 = 80t - 60t$ $120 = 20t$ $t = 120 / 20$ $t = 6$ So,

it will take the second train 6 hours to catch up to the first train. **Check:** In 6 hours, the second train travels $80 \text{ mph} \times 6 \text{ hours} = 480 \text{ miles}$. The first train travels for $6 + 2 = 8 \text{ hours}$. In 8 hours, it travels $60 \text{ mph} \times 8 \text{ hours} = 480 \text{ miles}$. The distances are equal, so the solution is correct.

3. Mixture Problems: Blending Quantities

Mixture problems involve combining two or more quantities with different properties (like concentrations or prices) to create a new mixture with a desired property. The key is to focus on the amount of the substance and its concentration (or value). **Example 3:** A chemist wants to make 10 liters of a 30% acid solution. She has a 20% acid solution and a 50% acid solution. How many liters of each solution should she mix?

Keywords: mixture, solution, acid, percentage, liters, combine, concentration **LSI Keywords:** chemical solutions, blending, proportions, solute, solvent **Solution:** Let x be the number of liters of the 20% acid solution. Let y be the number of liters of the 50% acid solution. We know two main things: 1. The total volume of the mixture is 10 liters. 2. The total amount of acid in the mixture. From point 1: $x + y = 10$ (Equation 1) From point 2: The amount of acid in the 20% solution is $0.20x$. The amount of acid in the 50% solution is $0.50y$. The amount of acid in

the final 30% solution is $0.30 * 10 = 3$ liters. So, the equation for the amount of acid is: $0.20x + 0.50y = 3$ (Equation 2) Now we have a system of equations: 1. $x + y = 10$ 2. $0.20x + 0.50y = 3$ From Equation 1, we can express x as: $x = 10 - y$. Substitute this into Equation 2: $0.20(10 - y) + 0.50y = 3$ Solve for y : $2 - 0.20y + 0.50y = 3$ $0.30y = 3 - 2$ $0.30y = 1$ $y = 1 / 0.30$ $y = 10 / 3$ liters So, she needs $10/3$ liters (approximately 3.33 liters) of the 50% acid solution. Now substitute the value of y back into $x = 10 - y$: $x = 10 - (10/3)$ $x = (30/3) - (10/3)$ $x = 20/3$ liters So, she needs $20/3$ liters (approximately 6.67 liters) of the 20% acid solution. **Check:** Total volume: $20/3 + 10/3 = 30/3 = 10$ liters. (Correct) Total acid: $(0.20 * 20/3) + (0.50 * 10/3) = (4/3) + (5/3) = 9/3 = 3$ liters. 30% of 10 liters is 3 liters. (Correct)

4. Work Problems: Teamwork Makes the Dream Work

Work problems deal with tasks being completed by one or more people or machines. The key concept here is the "rate of work." If someone can complete a job in ' x ' hours, their rate of work is $1/x$ of the job per hour. **Example 4:** Machine A can produce 100 widgets in 5 hours. Machine B can produce 100 widgets in 10 hours. How long will it take both machines working together to produce 100 widgets? **Keywords:** work, time, machine, produce, together, rate, job **LSI Keywords:** efficiency,

productivity, combined effort, task completion **Solution:** First, find the rate of work for each machine. Rate of Machine A (R_A) = 1 job / 5 hours = $1/5$ of the job per hour. Rate of Machine B (R_B) = 1 job / 10 hours = $1/10$ of the job per hour. When working together, their rates add up. Let 'T' be the time it takes for both machines to complete 1 job together. Combined Rate (R_{combined}) = $R_A + R_B$ $R_{\text{combined}} = 1/5 + 1/10$ To add these fractions, find a common denominator (which is 10): $R_{\text{combined}} = 2/10 + 1/10$ $R_{\text{combined}} = 3/10$ of the job per hour. The relationship is still $D = RT$, where D is the amount of work (1 job), R is the combined rate, and T is the time. 1 job = $(3/10 \text{ job/hour}) \times T \text{ hours}$ Solve for T: $T = 1 \text{ job} / (3/10 \text{ job/hour})$ $T = 10/3 \text{ hours}$ So, it will take both machines $10/3$ hours (or 3 and $1/3$ hours) to produce 100 widgets together. **Check:** In $10/3$ hours, Machine A completes $(1/5) * (10/3) = 10/15 = 2/3$ of the job. In $10/3$ hours, Machine B completes $(1/10) * (10/3) = 10/30 = 1/3$ of the job. Together, they complete $2/3 + 1/3 = 3/3 = 1$ whole job. (Correct)

5. Percentage and Discount Problems: Smart Shopping

These problems are incredibly practical, helping us understand sales, taxes, and financial growth. The core idea is understanding what a percentage represents (a fraction out of 100) and how to calculate it. **Example 5:** A

store is having a 25% off sale. If a shirt originally cost \$40, what is the sale price? If there is a 6% sales tax added to the sale price, what is the final price?

Keywords: percentage, discount, sale, original price, sale price, sales tax, final price **LSI Keywords:** percent off, savings, cost, markup, tax rate **Solution: Part 1:**

Calculate the sale price The discount is 25% of the original price. Discount amount = 25% of \$40 Discount amount = $0.25 * \$40 = \10 The sale price is the original price minus the discount. Sale price = Original price - Discount amount Sale price = $\$40 - \$10 = \$30$

Alternatively, if there is a 25% discount, you are paying $100\% - 25\% = 75\%$ of the original price. Sale price = 75% of \$40 Sale price = $0.75 * \$40 = \30 The sale price of the shirt is \$30. **Part 2: Calculate the final price with**

sales tax The sales tax is 6% of the sale price. Sales tax amount = 6% of \$30 Sales tax amount = $0.06 * \$30 = \1.80 The final price is the sale price plus the sales tax amount. Final price = Sale price + Sales tax amount Final price = $\$30 + \$1.80 = \$31.80$ Alternatively, if there is a 6% sales tax, you are paying $100\% + 6\% = 106\%$ of the sale price. Final price = 106% of \$30 Final price = $1.06 * \$30 = \31.80 The final price of the shirt with sales tax is \$31.80.

Tips for Tackling Any Algebra Word

1. **Read Carefully and Multiple Times:** Don't rush through the problem. Read it once to get the general idea, then again to identify key information.
2. **Identify the Unknowns:** What are you trying to find? Assign variables (like x , y , or descriptive letters) to these unknowns.
3. **Translate Words into Equations:** This is the core skill. Look for keywords that indicate mathematical operations (e.g., "is" means equals, "more than" means add, "times" means multiply, "of" often means multiply).
4. **Draw Diagrams or Make Tables:** Visual aids can be incredibly helpful, especially for distance, rate, and time problems or mixture problems.
5. **Check Your Answer:** Once you have a solution, plug it back into the original problem to see if it makes sense and satisfies all conditions.
6. **Break Down Complex Problems:** If a problem seems overwhelming, try to break it into smaller, manageable parts.
7. **Practice, Practice, Practice:** The more word problems you solve, the more comfortable you'll become with different types and strategies.

Conclusion: Algebra in Action

Word problems are not just academic exercises; they are the gateways to understanding how the logical world of mathematics applies to our everyday lives. By practicing these examples and applying the tips provided, you can build a strong foundation in algebraic problem-solving. Remember, every word problem is an opportunity to sharpen your analytical skills and to see the power of algebra in action. Keep practicing, and you'll find yourself increasingly confident in tackling any numerical challenge that comes your way!

Algebraic word problems serve as a bridge between abstract mathematical concepts and real-world applications, offering students a meaningful context to develop problem-solving skills. These problems require learners to interpret textual information, translate words into mathematical expressions or equations, and then solve for unknowns using algebraic techniques. By grounding equations in everyday scenarios, students not only practice computation but also build critical thinking and analytical reasoning—skills essential across science, engineering, economics, and everyday decision-making.

Understanding the Role of Word

Problems in Algebra

Word problems in algebra are far more than routine exercises; they are cognitive tools that challenge learners to decode language, identify relationships, and apply mathematical reasoning. Unlike isolated numerical drills, these problems contextualize variables, making them tangible and memorable. For example, instead of simply solving $2x = 10$, a word problem might ask, “A vendor sells apples at \$2 each. If total sales reach \$10, how many apples were sold?” This shift from abstraction to narrative fosters deeper comprehension and retention, aligning with how real-life problem-solving unfolds.

Key Features of Effective Algebra Word Problems

A well-crafted algebra word problem typically combines several core elements. First, it presents a clear, realistic scenario—often drawn from daily life such as budgeting, travel, or resource allocation—that students can relate to. Second, it embeds multiple steps requiring sequential reasoning: translating words into equations, isolating variables, and interpreting solutions within context. Third, these problems often involve multiple variables and relationships, encouraging learners to model complex systems rather than solving simple equations in isolation. Finally, authentic word problems reward conceptual

understanding over mechanical computation, emphasizing the “why” behind each step.

Classic Examples and Their Solutions

One common example involves a scenario where two friends are saving money. Suppose Mia saves \$15 per week and her friend Leo saves \$10 per week. If Mia starts with \$20 and Leo begins with \$40, after how many weeks will they have saved the same amount? To solve this, we set up equations: Mia’s savings are modeled by $15w + 20$, and Leo’s by $10w + 40$. Setting them equal gives $15w + 20 = 10w + 40$. Subtracting $10w$ from both sides yields $5w + 20 = 40$. Subtracting 20 results in $5w = 20$, so $w = 4$. Thus, after four weeks, both friends will have saved the same amount. Another illustrative problem concerns a car rental comparison. A car rental company charges a flat fee of \$50 plus \$0.20 per mile, while another charges \$30 plus \$0.30 per mile. After how many miles will the total cost be the same? Let m represent miles driven. The cost equations are $50 + 0.20m$ and $30 + 0.30m$. Equating them: $50 + 0.20m = 30 + 0.30m$. Subtracting $0.20m$ and 30 from both sides gives $20 = 0.10m$, so $m = 200$. At 200 miles, both rental plans cost the same. These examples demonstrate how algebra word problems mirror real financial decisions, helping students connect classroom knowledge to practical outcomes.

Broader Applications and Educational Benefits

Beyond classroom learning, algebraic word problems cultivate transferable skills. In STEM fields, they model physical systems, economic trends, and engineering constraints, enabling precise analysis and prediction. In business, they support budget forecasting and profit modeling. Moreover, solving these problems strengthens verbal comprehension, logical sequencing, and precision in communication—competencies vital in professional settings. Educators increasingly leverage word problems to promote engagement, reduce math anxiety, and nurture a mindset where challenges are approached systematically.

The Future of Algebra Word Problems in Education

As education evolves, so too does the design and delivery of algebra word problems. Digital platforms now offer interactive, adaptive problem sets that adjust complexity based on student performance, providing personalized learning paths. Augmented reality and real-time data integration allow students to solve problems rooted in dynamic, evolving scenarios—such as managing a virtual city's budget or tracking environmental changes. These innovations preserve the core value of contextual

learning while enhancing accessibility and relevance. Looking ahead, the continued emphasis on authentic, interdisciplinary problems ensures algebra remains not just a subject, but a powerful lens through which students interpret and shape the world. The enduring power of word problems lies in their ability to transform abstract symbols into meaningful stories—making algebra not just a set of rules, but a tool for understanding and innovation.

Unlocking Algebra: Navigating Word Problems with Clear Examples and Solutions

Algebra can often feel like a foreign language, a collection of symbols and equations divorced from the real world. However, at its core, algebra is a powerful tool for understanding and solving everyday problems. The bridge between abstract equations and practical application is built through **word problems in algebra**. These narrative scenarios require us to translate verbal descriptions into mathematical expressions, a skill that is fundamental to both academic success and real-world problem-solving.

This comprehensive guide will delve into various types of algebraic word problems, providing detailed explanations

and step-by-step solutions. We'll explore common problem categories, from age and distance to mixtures and financial scenarios, equipping you with the confidence and strategies to tackle any algebraic challenge. Whether you're a student struggling with homework or an adult looking to refresh your mathematical skills, understanding how to dissect and solve these problems is invaluable.

The beauty of algebra lies in its universality. The principles learned through solving these examples can be applied to countless situations, making them essential for anyone seeking to develop strong analytical and critical thinking abilities. Let's begin our journey into the world of algebraic word problems.

The Foundation: Translating Words into Equations

Before we dive into specific examples, it's crucial to understand the fundamental process of translating a word problem into a solvable algebraic equation. This involves several key steps:

1. Read Carefully and Identify the Unknowns:

Thoroughly read the problem, highlighting or noting down the quantities that are unknown. These will typically be represented by variables (like 'x', 'y', or 'n').

2. **Assign Variables:** Assign a letter (variable) to each unknown quantity. It's good practice to choose letters that are mnemonic (e.g., 'a' for age, 'd' for distance).
3. **Identify Relationships:** Determine how the unknown quantities relate to each other based on the information given in the problem. Look for keywords like "sum," "difference," "product," "quotient," "more than," "less than," "times," "is," etc.
4. **Formulate Equations:** Write down mathematical equations that represent these relationships. This is where you'll use the variables you've assigned.
5. **Solve the Equations:** Use algebraic techniques (like substitution, elimination, or inverse operations) to solve for the unknown variables.
6. **Check Your Answer:** Substitute your solution back into the original word problem or the formulated equations to ensure it makes sense and satisfies all the conditions.

Mastering this translation process is the key to unlocking success with all types of algebraic word problems.

Common Types of Algebraic Word Problems with Examples

Let's explore some of the most frequently encountered categories of word problems and work through them systematically.

1. Age Problems

Age problems often involve comparing the ages of two or more people at different points in time (present, past, or future). The core principle is to establish relationships between their ages.

Example 1: Simple Age Comparison

Problem: Sarah is 5 years older than her brother, Tom. Together, their ages sum to 27. How old is each of them?

Solution:

Step 1 & 2: Identify Unknowns and Assign Variables

Let Sarah's age be 's' and Tom's age be 't'.

Step 3 & 4: Identify Relationships and Formulate Equations

* "Sarah is 5 years older than her brother, Tom": $s = t + 5$ (Equation 1) * "Together, their ages sum to 27": $s + t = 27$ (Equation 2)

Step 5: Solve the Equations

We can use substitution. Substitute the expression for 's' from Equation 1 into Equation 2:

$$((t + 5) + t = 27)$$

$$(2t + 5 = 27)$$

$$(2t = 27 - 5)$$

$$(2t = 22)$$

$$(t = 11)$$

Now substitute the value of 't' back into Equation 1 to find 's':

$$(s = 11 + 5)$$

$$(s = 16)$$

Step 6: Check Your Answer Sarah is 16 and Tom is 11. Is Sarah 5 years older? Yes ($16 - 11 = 5$). Do their ages sum to 27? Yes ($16 + 11 = 27$). The solution is correct.

2. Distance, Rate, and Time Problems

These problems are based on the fundamental formula:

$$(\text{Distance} = \text{Rate} \times \text{Time}) \text{ (or } (d = r \times t)).$$

When objects are moving, we often consider scenarios involving them moving towards each other, away from each other, or at different speeds.

Example 2: Traveling Towards Each Other

Problem: Two trains leave opposite stations and travel towards each other on the same track. Train A travels at 60 mph, and Train B travels at 70 mph. If the stations are 390 miles apart, how long will it take for the trains to meet?

Solution:

Step 1 & 2: Identify Unknowns and Assign Variables

Let 't' be the time in hours until the trains meet.

Step 3 & 4: Identify Relationships and Formulate Equations

* Distance covered by Train A: $(d_A = 60t)$ *

Distance covered by Train B: $(d_B = 70t)$ *

When they meet, the sum of the distances they have traveled will equal the total distance between the stations: $(d_A + d_B = 390)$

Substitute the expressions for (d_A) and (d_B) :

$$(60t + 70t = 390)$$

Step 5: Solve the Equations $(130t = 390)$

$$(t = \frac{390}{130})$$

$$(t = 3)$$

Step 6: Check Your Answer In 3 hours, Train A will travel $(60 \text{ mph} \times 3 \text{ hours} = 180 \text{ miles})$. In 3 hours, Train B will travel $(70 \text{ mph} \times 3 \text{ hours} = 210 \text{ miles})$. The total distance covered is $(180 + 210 = 390 \text{ miles})$, which is the distance between the stations. The solution is correct.

3. Mixture Problems

Mixture problems involve combining two or more substances with different concentrations or values to create a mixture with a desired concentration or value. The key is to track the amount of the substance and its

concentration.

Example 3: Combining Solutions

Problem: A chemist needs to create 10 liters of a 20% saline solution. She has a 10% saline solution and a 30% saline solution. How many liters of each solution should she mix?

Solution:

Step 1 & 2: Identify Unknowns and Assign Variables

Let 'x' be the number of liters of the 10% solution. Let 'y' be the number of liters of the 30% solution.

Step 3 & 4: Identify Relationships and Formulate

Equations * The total volume of the mixture is 10 liters:
 $(x + y = 10)$ (Equation 1) * The amount of salt in the 10% solution is $(0.10x)$. * The amount of salt in the 30% solution is $(0.30y)$. * The amount of salt in the final 20% solution is $(0.20 \times 10 = 2)$ liters. * The total amount of salt in the mixture is the sum of the salt from the two initial solutions: $(0.10x + 0.30y = 2)$ (Equation 2)

Step 5: Solve the Equations From Equation 1, we can express (y) as $(y = 10 - x)$. Substitute this into Equation 2:

$$(0.10x + 0.30(10 - x) = 2)$$

$$(0.10x + 3 - 0.30x = 2)$$

$$(-0.20x + 3 = 2)$$

$$(-0.20x = 2 - 3)$$

$$(-0.20x = -1)$$

$$(x = \frac{-1}{-0.20})$$

$$(x = 5)$$

Now substitute the value of 'x' back into Equation 1:

$$(5 + y = 10)$$

$$(y = 10 - 5)$$

$$(y = 5)$$

Step 6: Check Your Answer We need 5 liters of the 10% solution and 5 liters of the 30% solution. Total volume: $(5 + 5 = 10)$ liters. Correct. Amount of salt from 10% solution: $(0.10 \times 5 = 0.5)$ liters. Amount of salt from 30% solution: $(0.30 \times 5 = 1.5)$ liters. Total salt: $(0.5 + 1.5 = 2)$ liters. Concentration of the final mixture: $(\frac{2 \text{ liters of salt}}{10 \text{ liters of solution}} = 0.20)$, or 20%. Correct.

4. Coin Problems

Coin problems involve scenarios where you have a collection of coins of different denominations, and you know the total number of coins and the total value. The challenge is to find out how many of each type of coin you have.

Example 4: Counting Coins

Problem: A cashier has a total of 30 bills in her drawer, consisting of \$5 bills and \$10 bills. The total value of the bills is \$200. How many of each denomination does she have?

Solution:

Step 1 & 2: Identify Unknowns and Assign Variables

Let 'f' be the number of \$5 bills. Let 't' be the number of \$10 bills.

Step 3 & 4: Identify Relationships and Formulate Equations

* Total number of bills: $(f + t = 30)$

(Equation 1) * Total value of the bills: $(5f + 10t = 200)$

(Equation 2)

Step 5: Solve the Equations From Equation 1, $(f = 30 - t)$. Substitute this into Equation 2:

$$(5(30 - t) + 10t = 200)$$

$$(150 - 5t + 10t = 200)$$

$$(150 + 5t = 200)$$

$$(5t = 200 - 150)$$

$$(5t = 50)$$

$$(t = 10)$$

Now substitute the value of 't' back into Equation 1:

$$(f + 10 = 30)$$

$$(f = 30 - 10)$$

$$(f = 20)$$

Step 6: Check Your Answer The cashier has 20 \$5 bills and 10 \$10 bills. Total number of bills: $(20 + 10 = 30)$. Correct. Total value: $((20 \times \$5) + (10 \times \$10) = \$100 + \$100 = \$200)$. Correct.

5. Work Problems

Work problems typically involve two or more individuals or entities working together to complete a task. The key concept is the rate at which each entity works, and how their rates combine when they work together.

Example 5: Combined Effort

Problem: It takes John 4 hours to paint a room, and it takes Mary 6 hours to paint the same room. If they work together, how long will it take them to paint the room?

Solution:

Step 1 & 2: Identify Unknowns and Assign Variables

Let 't' be the time in hours it takes them to paint the room together.

Step 3 & 4: Identify Relationships and Formulate Equations

* John's rate of work is $(\frac{1}{4})$ of the

room per hour. * Mary's rate of work is $\frac{1}{6}$ of the room per hour. * When they work together, their rates add up. The combined rate is $\frac{1}{t}$ of the room per hour.

The equation is: $\text{John's rate} + \text{Mary's rate} = \text{Combined rate}$

$$\frac{1}{4} + \frac{1}{6} = \frac{1}{t}$$

Step 5: Solve the Equations To add the fractions on the left side, find a common denominator, which is 12:

$$\frac{3}{12} + \frac{2}{12} = \frac{1}{t}$$

$$\frac{5}{12} = \frac{1}{t}$$

To solve for 't', we can take the reciprocal of both sides:

$$t = \frac{12}{5}$$

$$t = 2.4 \text{ hours.}$$

Step 6: Check Your Answer In 2.4 hours, John would paint $\frac{1}{4} \times 2.4 = 0.6$ of the room. In 2.4 hours, Mary would paint $\frac{1}{6} \times 2.4 = 0.4$ of the room. Together, they would paint $(0.6 + 0.4 = 1)$ whole room. The solution is correct.

Tips for Tackling Algebraic Word

Problems

Beyond the systematic approach, here are some additional tips to enhance your ability to solve algebraic word problems:

1. **Visualize the Problem:** For distance or geometry problems, drawing a diagram can be incredibly helpful in understanding the relationships between different parts.
2. **Break Down Complex Problems:** If a problem seems overwhelming, try to break it down into smaller, more manageable parts.
3. **Be Consistent with Units:** Ensure all your measurements are in the same units (e.g., all in miles, or all in hours) before setting up equations.
4. **Read the Question Again:** Before you start writing, re-read the problem to make sure you understand exactly what is being asked. After you solve, check that your answer directly addresses the question.
5. **Practice Regularly:** Like any skill, proficiency in solving algebraic word problems comes with consistent practice. Work through a variety of problems to expose yourself to different scenarios.
6. **Understand the Keywords:** Familiarize yourself with common keywords and their mathematical translations (e.g., "is" usually means "=", "of" often means multiplication, "per" implies division).

Questions & Answers About examples of word problems in algebra with solution

No	Question	Answer
1	What's a classic example of a word problem involving setting up and solving a linear equation?	A common example: 'Sarah has 5 apples and buys 3 more each week. How many weeks until she has 20 apples?' Let 'w' be the number of weeks. Equation: $5 + 3w = 20$. Solving: $3w = 15$, so $w = 5$ weeks.
2	Can you show me an algebra word problem that uses consecutive integers?	Sure! 'The sum of three consecutive integers is 51. Find the integers.' Let the first integer be 'x'. The next two are 'x+1' and 'x+2'. Equation: $x + (x+1) + (x+2) = 51$. Solving: $3x + 3 = 51$, $3x = 48$, $x = 16$. The integers are 16, 17, and 18.

3	What's a typical word problem that requires solving a quadratic equation?	Consider this: 'A rectangular garden has a length that is 4 meters more than its width. If its area is 60 square meters, what are its dimensions?' Let width be 'w'. Length is 'w+4'. Equation: $w(w+4) = 60$, or $w^2 + 4w - 60 = 0$. Factoring: $(w+10)(w-6) = 0$. Since width must be positive, $w = 6$ meters. Length is 10 meters.
4	How do I approach word problems involving mixtures or concentrations?	For mixtures: 'How many liters of a 20% saline solution must be added to 10 liters of a 50% saline solution to obtain a 30% solution?' Let 'x' be the liters of the 20% solution. Equation: $0.20x + 0.50(10) = 0.30(x+10)$. Solving: $0.20x + 5 = 0.30x + 3$, $2 = 0.10x$, so $x = 20$ liters.
5	What's an example of a word problem that involves rates and work?	Here's one: 'If Machine A can produce 100 widgets in 2 hours and Machine B can produce 100 widgets in 3 hours, how long will it take them to produce 100 widgets working together?' Rate of A = $100/2 = 50$ widgets/hr. Rate of B = $100/3$ widgets/hr. Combined rate = $50 + 100/3 = 250/3$ widgets/hr. Time = Total Work / Rate = $100 / (250/3) = 120/250 = 0.48$ hours (or 28.8 minutes).

6	Can you give me an algebra word problem that uses ratios?	Yes! 'The ratio of boys to girls in a class is 3:5. If there are 15 boys, how many students are in the class?' Let the number of boys be $3x$ and girls be $5x$. We know $3x = 15$, so $x = 5$. Number of girls = $5 * 5 = 25$. Total students = $15 + 25 = 40$.
7	What's a common word problem type involving distance, rate, and time?	A classic: 'Two cars leave the same point at the same time, traveling in opposite directions. One travels at 60 mph and the other at 70 mph. How long will it take for them to be 520 miles apart?' Let ' t ' be the time. Distance of car 1 = $60t$. Distance of car 2 = $70t$. Total distance = $60t + 70t = 520$. Solving: $130t = 520$, so $t = 4$ hours.
8	How can algebra be used to solve age-related word problems?	Example: 'John is twice as old as Mary. In 5 years, John will be 8 years older than Mary. How old are they now?' Let Mary's current age be ' m '. John's current age is ' $2m$ '. In 5 years, Mary is ' $m+5$ ' and John is ' $2m+5$ '. Equation: $2m+5 = (m+5) + 8$. Solving: $2m+5 = m+13$, $m = 8$. Mary is 8, John is 16.
